

Abstract

The present invention provides a website service method. First, a specific demand event to be searched is set at one's own server, and several website addresses, BBS addresses, or related server addresses are inputted. A searching
5 program then actively collects related data, and stores the data into a database. Next, the server picks out communication information and mating data and then actively invites the supplier and the demander to enter the website. After the supplier and the demander are informed, they can connect to the website to register and input article data or demand conditions. The website performs
10 relational mating of supply and demand and then displays the mating result. If the requirements of the supplier and the demander are met, they can contact each other through data provided by the database. Supply and demand can thus be more effectively and quickly accomplished.
